

# WHEN ARE THE CAYLEY-SALMON LINES CONJUGATE?

JAYDEEP CHIPALKATTI

**ABSTRACT:** Given six points on a conic, Pascal's theorem gives rise to a well-known configuration called the *hexagrammum mysticum*. It consists of, amongst other things, twenty Steiner points and twenty Cayley-Salmon lines. It is a classical theorem due to von Staudt that the Steiner points fall into ten conjugate pairs with reference to the conic; but this is not true of the C-S lines for a general choice of six points. It is shown in this paper that the C-S lines are pairwise conjugate precisely when the original sextuple is *tri-involutive*. The variety of tri-involutive sextuples turns out to be arithmetically Cohen-Macaulay of codimension two. We determine its  $SL_2$ -equivariant minimal resolution.

## 1. INTRODUCTION

The main result of this paper involves the so-called Cayley-Salmon lines, which form a subconfiguration of the famous *hexagrammum mysticum* of Pascal. I have retained the notation of my earlier paper [3], but some of the background is reproduced below for ease of reading.

**1.1. Pascal lines.** Let  $\mathcal{K}$  denote a nonsingular conic in the complex projective plane. Consider six distinct points  $\Gamma = \{A, B, C, D, E, F\}$  on  $\mathcal{K}$ , arranged as an array  $\begin{bmatrix} A & B & C \\ F & E & D \end{bmatrix}$ . Pascal's theorem says that the three cross-hair intersection points

$$AE \cap BF, \quad AD \cap CF, \quad BD \cap CE$$

(corresponding to the three minors of the array) are collinear. The line containing them (usually called the Pascal line, or just the Pascal) is denoted by  $\left\{ \begin{array}{ccc} A & B & C \\ F & E & D \end{array} \right\}$ . It appears as  $k(1, 23)$  in the usual labelling schema for Pascals (see [3, §2]). Similarly, the lines  $k(2, 13)$  and  $k(3, 12)$  are respectively equal to

$$\left\{ \begin{array}{ccc} A & B & C \\ D & F & E \end{array} \right\} \quad \text{and} \quad \left\{ \begin{array}{ccc} A & B & C \\ E & D & F \end{array} \right\}.$$

**1.2. Steiner Points.** It was proved by Steiner that the lines  $k(1, 23), k(2, 13), k(3, 12)$  are concurrent, and their common point of intersection is called a Steiner point, denoted by<sup>1</sup>  $G[123]$ . This is understood to hold for any three indices in the same pattern. If SIX denotes the set  $\{1, 2, \dots, 6\}$ , then for any three indices  $x, y, z \in \text{SIX}$ , the Pascals

$$k(x, yz), \quad k(y, xz), \quad k(z, xy),$$

intersect in the point  $G[xyz]$ , giving altogether  $\binom{6}{3} = 20$  Steiner points. This theorem, together with similar incidence theorems mentioned below may be found in Salmon's [16, Notes], which also contains references to earlier literature on the subject. Salmon does not use the  $k$ -notation however, but there is a detailed explanation of it in Baker's [2, Note II].

**1.3. Kirkman points and Cayley-Salmon lines.** It is a theorem due to Kirkman that the lines

$$k(1, 23), \quad k(1, 24), \quad k(1, 34)$$

are concurrent, and their common point of intersection is called the Kirkman point  $K[1, 234]$ . There are 60 such points  $K[w, xyz]$ , corresponding to indices  $w \in \text{SIX}, \{x, y, z\} \subseteq \text{SIX} \setminus \{w\}$ . It was proved by Cayley and Salmon that the Kirkman points

$$K[4, 123], \quad K[5, 123], \quad K[6, 123]$$

---

<sup>1</sup>It is a notational convention that 123 stands for the set  $\{1, 2, 3\}$ , and hence the order of indices is irrelevant. This applies to all similar situations, so that  $k(1, 23)$  is the same as  $k(1, 32)$  etc.

are collinear, and the common line containing them is called the Cayley-Salmon line<sup>2</sup>  $g(123)$ . There are 20 such lines  $g(xyz)$  for  $\{x, y, z\} \subseteq \text{SIX}$ . It is also the case that  $g(xyz)$  contains the Steiner point  $G[xyz]$ .

For a *general* choice of six points  $\Gamma$ , all of the lines and points above are pairwise distinct, and there are no further incidences apart from those already mentioned. (It may happen that some of the lines and points become undefined for special positions of  $\Gamma$ ; this will be explained as and when necessary.) Using the standard notation for incidence correspondences (see [10]), the situation for a general  $\Gamma$  can be summarised as follows:

- The  $K$ -points and  $g$ -lines make a  $(60_1, 20_3)$  configuration. That is to say, each of the 60  $K$ -points lies on one  $g$ -line, and each of the 20  $g$ -lines contains three  $K$ -points.
- The  $K$ -points and  $k$ -lines make a  $(60_3, 60_3)$  configuration.
- The  $G$ -points and  $k$ -lines make a  $(20_3, 60_1)$  configuration.
- The  $G$ -points and  $g$ -lines make a  $(20_1, 20_1)$  configuration.

We have throughout used uppercase letters for points, and lowercase letters for lines. The governing pattern is that, if the  $A$ -points and  $b$ -lines form an  $(r_s, t_u)$  configuration, then the  $B$ -points and  $a$ -lines form a  $(t_u, r_s)$  configuration.<sup>3</sup> It is tempting to conjecture that this numerical duality should be explainable as a pole-polar duality, but this is surprisingly not so (cf. [11, p. 194]). The following pair of facts signals a breakdown in symmetry. Assume  $\Gamma$  to be general, and let  $\{u, v, w, x, y, z\} = \text{SIX}$ . Then

- The points  $G[uvw]$  and  $G[xyz]$  are conjugate with respect to  $\mathcal{K}$ ; that is to say, the polar line of  $G[uvw]$  passes through  $G[xyz]$  and conversely. This is a theorem due to von Staudt (see [18] or [14, §86.2]).
- The lines  $g(uvw)$ ,  $g(xyz)$  are not conjugate; that is to say, the pole of  $g(uvw)$  does not lie on  $g(xyz)$ . This is easily checked with an example; see §2.2 below.

It is natural to ask whether the  $g$ -lines are in fact pairwise conjugate for *special* positions of  $\Gamma$ . The main result of this paper answers this question.

**1.4. The tri-involutive configuration.** Recall that  $\mathcal{K}$  is isomorphic to the projective line  $\mathbb{P}^1$ . We will say that a sextuple  $\Gamma$  is *tri-involutive*, if it is projectively equivalent to

$$\left\{ 0, 1, \infty, p, \frac{p-1}{p}, \frac{1}{1-p} \right\},$$

---

<sup>2</sup>The illustrious 27 lines on a nonsingular cubic surface (see [9, Ch. 4]) are also sometimes called the Cayley-Salmon lines. Although our context is different, there is, in fact, a thematic connection between the geometry of the 27 lines and the *hexagrammum mysticum* (see [15]).

<sup>3</sup>There are an additional fifteen  $i$ -lines and fifteen  $I$ -points which also obey this pattern, but we will not pursue this digression. See the notes by Baker and Salmon referred to above.

for some  $p \in \mathbb{P}^1$ . (The rationale behind this name will be clarified in §2.4. The configuration may well have been classically known in some form, but it arose in [3, §4.5] in the course of solving a different problem.)

Since the points are assumed distinct,

$$p \neq 0, 1, \infty, \frac{1 \pm \sqrt{-3}}{2}.$$

It may happen that the three Kirkman points  $K[w, xyz], w \in \text{SIX} \setminus \{x, y, z\}$  all coincide, so that the line  $g(xyz)$  becomes undefined. A complete list of such cases is given in §4.9.

1.5. We will say that a sextuple  $\Gamma$  satisfies Cayley-Salmon conjugacy (CSC), if the following property holds: The lines  $g(uvw)$  and  $g(xyz)$  are conjugate, whenever both are defined and  $\{u, v, w, x, y, z\} = \text{SIX}$ .

This is the main result of the paper:

**Theorem 1.1.** The following statements are equivalent:

- (1)  $\Gamma$  is tri-involutive.
- (2)  $\Gamma$  satisfies CSC.

Let  $\Omega$  denote the Zariski closure of the subset of tri-involutive sextuples inside

$$\text{Sym}^6 \mathcal{K} \simeq \text{Sym}^6 \mathbb{P}^1 \simeq \mathbb{P}^6.$$

It is a four-dimensional irreducible projective subvariety. (The  $p$  contributes one parameter, and the additional three come from  $SL_2$  acting on  $\mathbb{P}^1$ .) In §3, we will determine the group of symmetries of a generic tri-involutive sextuple and use it to calculate the degree of  $\Omega$ . The main theorem is proved in §4; it relies upon the properties of a collection of invariant polynomials associated to 3-element subsets of SIX. These properties were discovered by explicitly calculating and factoring these polynomials in MAPLE.

The  $SL_2$ -equivariant minimal resolution of the ideal of  $\Omega$  is determined in the concluding section. It implies that  $\Omega$  is an arithmetically Cohen-Macaulay subvariety of  $\mathbb{P}^6$ .

## 2. PRELIMINARIES

2.1. The base field is throughout  $\mathbb{C}$ . As in [3, §3], let  $S_d$  denote the vector space of homogeneous polynomials of degree  $d$  in the variables  $\{x_1, x_2\}$ . We identify the projective plane with  $\mathbb{P}S_2$ , and  $\mathcal{K}$  with the image of the Veronese imbedding  $\mathbb{P}S_1 \longrightarrow \mathbb{P}S_2$ . A nonzero quadratic form in the  $x_i$  simultaneously represents a point in  $\mathbb{P}^2$  and its polar line with respect to  $\mathcal{K}$ . All the line-intersections or point-joins can then be calculated as transvectants of binary forms. In particular,

two lines represented by quadratic forms  $\lambda$  and  $\mu$  are conjugate exactly when the transvectant  $(\lambda, \mu)_2$  is zero.

The sextuple  $\Gamma = \{z_1, \dots, z_6\} \subseteq \mathbf{C} \cup \{\infty\} = \mathbb{P}^1$  is identified with the sextic form  $\prod_{i=1}^6 (x_1 - z_i x_2)$ . (If  $z_i = \infty$ , we interpret the corresponding factor as  $x_2$ .) In this way,  $\Gamma$  can be seen as a point of  $\mathbb{P}S_6 \simeq \mathbb{P}^6$ .

2.2. For instance, consider the sextuple

$$A = 0, \quad B = 1, \quad C = \infty, \quad D = -1, \quad E = 3, \quad F = -5.$$

Then  $E$  is represented by  $(x_1 - 3x_2)^2$ , and  $C$  by  $x_2^2$  etc. Then the line  $EC$  corresponds to

$$((x_1 - 3x_2)^2, x_2^2)_1 = x_2(x_1 - 3x_2),$$

and one can calculate any required line or point from §1. In particular,  $g(123)$  is given by the form  $3x_1^2 - 26x_1x_2 - 5x_2^2$ . All the other  $g$ -lines are calculated similarly, and then it is straightforward to check that

$$(g(123), g(\alpha))_2 \neq 0,$$

for any 3-element subset  $\alpha \subseteq \text{SIX}$ . That is to say,  $g(123)$  is not conjugate to any C-S line. Since CSC is a closed condition on sextuples, it follows that a general sextuple does not satisfy CSC.

2.3. Recall that the cross-ratio of four ordered points on  $\mathbb{P}^1$  is defined to be

$$\langle z_1, z_2, z_3, z_4 \rangle = \frac{(z_1 - z_3)(z_2 - z_4)}{(z_1 - z_4)(z_2 - z_3)}.$$

If  $r$  denotes the original cross-ratio, then permuting the points in all possible ways gives six variants (see [17, Ch. 1]), namely

$$r, \quad \frac{1}{r}, \quad 1 - r, \quad \frac{1}{1 - r}, \quad \frac{r - 1}{r}, \quad \frac{r}{r - 1}.$$

One can reformulate the notion of tri-involutivity in terms of cross-ratios. As in [3, §3], consider the set of letters  $\text{LTR} = \{\mathbb{A}, \mathbb{B}, \mathbb{C}, \mathbb{D}, \mathbb{E}, \mathbb{F}\}$ , and define a *hexad* to be an injective map  $\text{LTR} \xrightarrow{h} \mathcal{K}$ . Write  $h(\mathbb{A}) = A$ ,  $h(\mathbb{B}) = B$ , and so on for the corresponding points on  $\mathcal{K}$ . Then a sextuple  $\Gamma$  is tri-involutive, if and only if there exists a hexad with image  $\Gamma$  such that

$$\langle A, B, C, F \rangle = \langle B, C, A, E \rangle = \langle C, A, B, D \rangle. \quad (2.1)$$

Indeed, if we let  $A = 0$ ,  $B = 1$ ,  $C = \infty$ , and if  $p$  denotes this common cross-ratio, then

$$D = p, \quad E = \frac{p - 1}{p}, \quad F = \frac{1}{1 - p}. \quad (2.2)$$

FIGURE 1. A sextuple in involution

2.4. Recall ([3, §3]) that a sextuple  $\Gamma$  is said to be in involution (see Figure 1), if there exists a point  $Q \in \mathbb{P}^2 \setminus \mathcal{K}$  and three lines  $L, L', L''$  through  $Q$  such that  $\Gamma = \mathcal{K} \cap (L \cup L' \cup L'')$ . One says that  $Q$  is a centre of involution for  $\Gamma$ .

Now a tri-involutive sextuple has the peculiarity that it has three such centres, which are in fact collinear. (This is explained at length in [3, §4.5].) Observe that in Figure 2 on the next page, each of the three points  $Q_4, Q_5, Q_6$  is a centre of involution in such a way that

- $AE, CD, BF$  intersect in  $Q_4$ ,
- $AF, CE, BD$  intersect in  $Q_5$ ,
- $AD, BE, CF$  intersect in  $Q_6$ .

2.5. **The exotic isomorphism.** It is well-known that the permutation group on six objects has a unique outer automorphism (see [6] or [12]). Part of its charm is that it is implicated everywhere in the geometry of the *hexagrammum mysticum*. We will use it in the following version: let  $\mathfrak{S}(X)$  denote the permutation group on the set  $X$ . Then the following symmetric table defines an isomorphism  $\mathfrak{S}(\text{LTR}) \xrightarrow{\zeta} \mathfrak{S}(\text{SIX})$ .

FIGURE 2. A tri-involutive sextuple

	A	B	C	D	E	F
A		14.25.36	16.24.35	13.26.45	12.34.56	15.23.46
B	14.25.36		15.26.34	12.35.46	16.23.45	13.24.56
C	16.24.35	15.26.34		14.23.56	13.25.46	12.36.45
D	13.26.45	12.35.46	14.23.56		15.24.36	16.25.34
E	12.34.56	16.23.45	13.25.46	15.24.36		14.26.35
F	15.23.46	13.24.56	12.36.45	16.25.34	14.26.35	

For instance, the entry in row  $\mathbb{A}$  and column  $\mathbb{B}$  is 14.25.36, and hence  $\zeta$  takes the transposition  $(\mathbb{A} \mathbb{B})$  to the element  $(1\ 4)(2\ 5)(3\ 6)$  of cycle type  $2 + 2 + 2$ . In the reverse direction,  $\zeta^{-1}$  takes  $(1\ 2)$  to  $(\mathbb{A} \mathbb{E})(\mathbb{B} \mathbb{D})(\mathbb{C} \mathbb{F})$ , because these are precisely the positions in the table where the pair 12 appears. The action of  $\zeta$  or  $\zeta^{-1}$  on an arbitrary element can be read off by writing it as a product of transpositions.

### 3. THE SYMMETRIES OF A TRI-INVOLUTIVE SEXTUPLE

3.1. Let  $\Gamma$  be a tri-involutive sextuple. We will say that a hexad LTR  $\xrightarrow{h} \Gamma$  is an *alignment* if equations (2.1) hold. It would be convenient to characterise all shuffles of LTR which preserve this property. After an automorphism of  $\mathbb{P}^1$ , we may assume that  $h$  is given by

$$\mathbb{A} \rightarrow 0, \quad \mathbb{B} \rightarrow 1, \quad \mathbb{C} \rightarrow \infty, \quad \mathbb{D} \rightarrow p, \quad \mathbb{E} \rightarrow \frac{p-1}{p}, \quad \mathbb{F} \rightarrow \frac{1}{1-p}.$$

Let  $\Theta(p)$  denote the subgroup of bijections LTR  $\xrightarrow{\eta} \text{LTR}$  such that

$$\langle A', B', C', F' \rangle = \langle B', C', A', E' \rangle = \langle C', A', B', D' \rangle, \quad (3.1)$$

where  $A'$  stands for  $h \circ \eta(\mathbb{A})$  and similarly for  $B'$  etc. The group is completely determined by formal properties of cross-ratios for a general value of  $p$ , and as such is independent of  $p$ . We will denote the generic case simply by  $\Theta$ , and proceed to determine its structure. (The group may be larger for special values of  $p$ ; see §5.3 below.) This will be used later to find the degree of the locus of tri-involutive sextuples.

With the alignment as above,

$$\langle E, F, D, B \rangle = \langle F, D, E, A \rangle = \langle D, E, F, C \rangle = p, \quad (3.2)$$

and hence  $(\mathbb{A} \mathbb{E})(\mathbb{B} \mathbb{F})(\mathbb{C} \mathbb{D}) \in \Theta$ . More generally, it is easy to verify that

$$(x x') (y y') (z z') \in \Theta, \quad (3.3)$$

whenever

$$\{x, y, z\} = \{\mathbb{A}, \mathbb{B}, \mathbb{C}\}, \quad \text{and} \quad \{x', y', z'\} = \{\mathbb{D}, \mathbb{E}, \mathbb{F}\}.$$

(For instance, if  $\eta = (\mathbb{A} \mathbb{D})(\mathbb{B} \mathbb{F})(\mathbb{C} \mathbb{E})$ , then each term in (3.1) becomes  $p/(p-1)$ .) It immediately follows that  $(x x') (y y') \in \Theta$  whenever  $x, x' \in \{\mathbb{A}, \mathbb{B}, \mathbb{C}\}$  and  $y, y' \in \{\mathbb{D}, \mathbb{E}, \mathbb{F}\}$ . Moreover, since  $(\mathbb{A} \mathbb{B})(\mathbb{D} \mathbb{E})(\mathbb{A} \mathbb{C})(\mathbb{D} \mathbb{E}) = (\mathbb{A} \mathbb{B} \mathbb{C})$  etc, every 3-cycle in either  $\mathfrak{S}(\{\mathbb{A}, \mathbb{B}, \mathbb{C}\})$  or  $\mathfrak{S}(\{\mathbb{D}, \mathbb{E}, \mathbb{F}\})$  is in  $\Theta$ .

**Proposition 3.1.** For a general value of  $p$ , the elements in (3.3) generate  $\Theta$ .

PROOF. Let  $\Theta' \subseteq \Theta$  denote the subgroup they generate, and consider the subgroup

$$\Phi = \mathfrak{S}(\{1, 2, 3\}) \times \mathfrak{S}(\{4, 5, 6\}), \quad (3.4)$$

of  $\mathfrak{S}(\text{SIX})$ . We claim that there is an equality  $\zeta(\Theta') = \Phi$ . Indeed, the table in §2.5 shows directly that  $\zeta$  takes the six elements in (3.3) to the 2-cycles  $(x x')$ , where  $x, x'$  are both in  $\{1, 2, 3\}$  or in  $\{4, 5, 6\}$ . (For instance,  $(\mathbb{A} \mathbb{E})(\mathbb{B} \mathbb{F})(\mathbb{C} \mathbb{D})$  goes to  $(5 6)$ .) This proves the claim.

Now assume that  $\Theta' \subsetneq \Theta$ , and let  $z \in \zeta(\Theta) \setminus \Phi$  denote an element with the maximum number of fixed points. It must be the case that  $z$  takes elements in  $\{1, 2, 3\}$  to  $\{4, 5, 6\}$  and conversely; for if not, one could increase the number of fixed points by multiplying it by an element of  $\Phi$ .

But then after conjugation by an element of  $\Phi$ , one may assume  $z$  to be one of the following:  $(1\ 4), (1\ 4)(2\ 5), (1\ 4)(2\ 5)(3\ 6), (1\ 4\ 2\ 5), (1\ 4\ 2\ 5)(3\ 6), (1\ 4\ 2\ 5\ 3\ 6)$ . Now apply  $\zeta^{-1}$  to each of these, and check that none of the images belongs to  $\Theta$ . This proves that  $\Theta' = \Theta$ .  $\square$

It follows that  $|\Theta| = 36$ . The isomorphism  $\Theta \simeq \Phi$  shows a common phenomenon surrounding the exotic isomorphism; namely a complicated structure on one side of  $\zeta$  often appears as a simpler structure on the other side.

3.2. Now let  $\Omega \subseteq \mathbb{P}^6$  denote the Zariski closure of the set of tri-involutive sextuples. It is an irreducible projective fourfold.

**Proposition 3.2.** The degree of  $\Omega$  is 16.

The proof will emerge from the discussion below. If  $z \in \mathcal{K}$  is an arbitrary point, then  $\{\Gamma \in \mathbb{P}^6 : z \in \Gamma\}$  is a hyperplane in  $\mathbb{P}^6$ . Since the degree of  $\Omega$  is the number of points in its intersection with four general hyperplanes, we are reduced to the following question: Given a set of four general points  $Z = \{z_1, \dots, z_4\} \subseteq \mathcal{K} \simeq \mathbb{P}^1$ , find the number of tri-involutive sextuples  $\Gamma$  such that  $Z \subseteq \Gamma$ . In other words, find all tri-involutive extensions of  $Z$ .

Let the variables  $a, b, \dots, f$  respectively stand for the coordinates of  $A, B, \dots, F$  on  $\mathcal{K}$ . Then conditions (2.1) correspond to equations

$$\frac{(a-c)(b-f)}{(a-f)(b-c)} = \frac{(b-a)(c-e)}{(b-e)(c-a)} = \frac{(c-b)(a-d)}{(c-d)(a-b)}. \quad (3.5)$$

3.3. By an *assignment*, we will mean an injective map  $Z \xrightarrow{u} \{a, \dots, f\}$ . Given such an assignment, say

$$z_1 \rightarrow c, \quad z_2 \rightarrow e, \quad z_3 \rightarrow a, \quad z_4 \rightarrow d,$$

we abbreviate it by  $[c, e, a, d]$ . Now substitute  $c = z_1, \dots, d = z_4$  into (3.5), and solve for the remaining unknowns  $b$  and  $f$ . Depending on the number of solutions so obtained, one would get one or more tri-involutive sextuples  $\Gamma$  containing  $Z$ . It is clear that every extension must come from an assignment. The group  $\Theta$  acts naturally on the set of assignments by permuting the  $a, \dots, f$ , and two assignments which are in the same orbit have the same extensions. Given  $u$  as above, consider the integer  $n(u) = \text{card}(\text{image}(u) \cap \{a, b, c\})$ . It must be either 1, 2 or 3.

3.4. Assume  $n(u) = 3$ . After an action by an element of  $\Theta$ , we may assume that  $u$  is one of the following:

$$[d, a, b, c], \quad [a, d, b, c], \quad [a, b, d, c], \quad [a, b, c, d]. \quad (3.6)$$

(For example,  $[c, a, f, b]$  can be changed to  $[a, c, e, b]$  by  $(\mathbb{A}\mathbb{C})(\mathbb{E}\mathbb{F})$ , and then to  $[a, b, d, c]$  by  $(\mathbb{B}\mathbb{C})(\mathbb{D}\mathbb{E})$ .) In each case, (3.5) give linear equations for the remaining variables  $e$  and  $f$  which determine them uniquely. For instance, if we let the  $z_i$  to be respectively  $0, 1, \infty, r$ , then the

$[d, a, b, c]$  case gives the extension  $Z \cup \left\{ \frac{r^2-r+1}{r}, r^2 - r + 1 \right\}$ . The remaining cases in (3.6) give three more extensions by the following enlargements of  $Z$ :

$$\left\{ \frac{r^2}{r-1}, r - r^2 \right\}, \quad \left\{ \frac{r}{r^2 - r + 1}, \frac{r^2}{r^2 - r + 1} \right\}, \quad \left\{ \frac{1}{1-r}, \frac{r-1}{r} \right\}.$$

Thus altogether we get four extensions. The assumption  $n(u) = 1$  gives nothing new, since we are back to  $n(u) = 3$  after an action by  $(\mathbb{A} \mathbb{D}) (\mathbb{B} \mathbb{E}) (\mathbb{C} \mathbb{F})$ .

3.5. If  $n(u) = 2$ , then after an action of  $\Theta$  we may assume that  $\text{image}(u) = \{a, b, e, f\}$ . We can then reduce further to one of the following six cases:

$$[a, b, x, y], \quad [a, x, b, y], \quad [a, x, y, b], \quad \text{where } \{x, y\} = \{e, f\}.$$

(For instance,  $[f, b, a, e]$  is changed to  $[b, f, e, a]$  by  $(\mathbb{A} \mathbb{E}) (\mathbb{B} \mathbb{F}) (\mathbb{C} \mathbb{D})$ , and then to  $[a, e, f, b]$  by  $(\mathbb{A} \mathbb{B}) (\mathbb{E} \mathbb{F})$ .) Given any such  $u$ , the first pair of equations in (3.5) gives a quadratic in  $c$ , and either of its roots will determine the value of  $d$  uniquely. Thus we get  $6 \times 2 = 12$  extensions altogether, and the fact that they are generically distinct is verified by a direct calculation as above. Thus  $\deg \Omega = 4 + 12 = 16$ .  $\square$

#### 4. THE CAYLEY-SALMON POLYNOMIALS

Consider the graded polynomial ring  $\mathfrak{P} = \mathbb{C}[a, b, c, d, e, f]$ . One can formulate the CSC condition as the vanishing of certain homogeneous polynomials in  $\mathfrak{P}$ ; this will lead to a proof of the main theorem.

4.1. As indicated earlier, each of the lines and points mentioned in §1 is represented by a quadratic form in  $x_1$  and  $x_2$ , with coefficients in  $\mathfrak{P}$ . For instance, the line  $k(1, 23)$  appears as  $\frac{1}{4}(c - d)$  times  $(c f - c e - a d - b f + b d + a e) x_1^2 + \cdots + (a c e f - a c d e + b c d f - b c e f + a b d e - a b d f) x_2^2$ .

Since  $c - d \neq 0$ , we are free to ignore the extraneous multiplicative factor, and this will always be done in the sequel. Henceforth we will not write out such forms explicitly, since the expressions are generally lengthy and not much is to be learned by merely looking at them. I have programmed the entire procedure in MAPLE, and the structure of the polynomials  $\mathcal{C}_\alpha$  described below was discovered in this way.

4.2. If quadratic forms  $Q, Q'$  represent the lines  $g(123), g(456)$ , then the vanishing of  $(Q, Q')_2$  is the necessary and sufficient condition for the lines to be conjugate. We denote this expression (shorn of extraneous multiplicative factors) by  $\mathcal{C}_{123}$  or  $\mathcal{C}_{456}$ ; and similarly define the *Cayley-Salmon polynomial*  $\mathcal{C}_\alpha \in \mathfrak{P}$  for each 3-element set  $\alpha \subseteq \text{SIX}$ . (Thus,  $\mathcal{C}_\alpha = C_{\text{SIX} \setminus \alpha}$  by construction.) It turns out that each  $\mathcal{C}_\alpha$  is homogeneous of degree 18; moreover, it is a product of six irreducible factors

which exhibit a high degree of symmetry. We will describe the structure of  $\mathcal{C}_{123}$  in detail, and then the action of the permutation group can be used to infer it for any  $\mathcal{C}_\alpha$ .

An explicit factorisation (done in MAPLE) shows that

$$\mathcal{C}_{123} = L_1 L_2 L_3 M_4 M_5 M_6,$$

where each  $L_i$  and  $M_j$  is a homogeneous cubic in  $a, \dots, f$ . (The factors are determined only up to nonzero multiplicative scalars, but this will cause no difficulty.) For instance,

$$L_1 = (cde + bcd + adf + abe + abf + bef) - (acd + bde + cdf + bce + acf + aef). \quad (4.1)$$

The following discussion will clarify how the remaining factors are thereby determined, and why they are so labelled.

4.3. The group  $\mathfrak{S}(\text{LTR})$  acts naturally on  $\mathfrak{P}$ , and so does the group  $\mathfrak{S}(\text{SIX})$  via  $\zeta^{-1}$ . Let  $G = G_{123} = G_{456}$  denote the subgroup of  $\mathfrak{S}(\text{SIX})$  generated by  $\mathfrak{S}(\{1, 2, 3\})$  and  $\mathfrak{S}(\{4, 5, 6\})$ , together with all elements of the form  $(xx')(yy')(zz')$ , where  $\{x, y, z\} = \{1, 2, 3\}$  and  $\{x', y', z'\} = \{4, 5, 6\}$ . In other words,  $G$  is the subset of elements in  $\mathfrak{S}(\text{SIX})$  which stabilise the unordered pair of sets  $\{\{1, 2, 3\}, \{4, 5, 6\}\}$ .

A direct calculation shows that  $G$  permutes the set of factors  $\mathcal{F}_{123} = \{L_1, L_2, L_3, M_4, M_5, M_6\}$ ; specifically, we have a homomorphism  $G \longrightarrow \mathfrak{S}(\mathcal{F}_{123})$  given by

$$\begin{aligned} (1\ 2) &\longrightarrow (L_1\ L_2), & (1\ 3) &\longrightarrow (L_1\ L_3), \\ (4\ 5) &\longrightarrow (M_4\ M_5), & (4\ 6) &\longrightarrow (M_4\ M_6), \\ (1\ 4)(2\ 5)(3\ 6) &\longrightarrow (L_1\ M_4)(L_2\ M_5)(L_3\ M_6). \end{aligned}$$

This is interpreted as follows. Since  $\zeta^{-1}(1\ 2) = (\mathbb{A}\ \mathbb{E})(\mathbb{B}\ \mathbb{D})(\mathbb{C}\ \mathbb{F})$ , the simultaneous substitution

$$a \rightarrow e, \quad e \rightarrow a, \quad b \rightarrow d, \quad d \rightarrow b, \quad c \rightarrow f, \quad f \rightarrow c,$$

interchanges  $L_1$  and  $L_2$ . The same recipe applies throughout; for instance, since

$$\zeta^{-1}((1\ 4)(2\ 5)(3\ 6)) = (\mathbb{A}\ \mathbb{B}),$$

the simultaneous substitution  $a \rightarrow b, b \rightarrow a$  acts as the permutation  $(L_1\ M_4)(L_2\ M_5)(L_3\ M_6)$ .

The  $L_i$  and  $M_j$  are labelled so as to harmonise with the action of  $G$ . Since this action is transitive on  $\mathcal{F}_{123}$ , each of the remaining factors  $L_2, \dots, M_6$  is obtainable by a change of variables in  $L_1$ .

4.4. **Invariance.** Consider a fractional linear transformation (FLT)

$$\mu(z) = \frac{pz + q}{rz + s},$$

where  $p, q, r, s$  and  $z$  are, at the moment, seen as formal indeterminates. Then a calculation shows that

$$L_1(\mu(a), \dots, \mu(f)) = \frac{(ps - qr)^3}{(ra + s) \dots (rf + s)} L_1(a, \dots, f).$$

In other words,  $L_1$  is an invariant for the action of FLTs on ordered sextuples in  $\mathbb{P}^1$ . A general theory of such functions may be found in [7, §1].

4.5. Given a hexad  $\text{LTR} \xrightarrow{h} \Gamma \subseteq \mathbf{C}$ , one can evaluate each of the polynomials above by substituting  $a = h(\mathbb{A}), \dots, f = h(\mathbb{F})$ . We will disallow the value  $\infty$  for simplicity, although it would not have been difficult to account for this possibility.

**Proposition 4.1.** Assume that  $h$  is an alignment. Then  $M_4 = M_5 = M_6 = 0$ .

PROOF. By the invariance mentioned above, the vanishing is unaffected by an FLT of  $\Gamma$ , hence we may assume  $a = 1, b = 0, c = -1$ . If  $t$  denotes the common cross-ratio in (2.1), then we must have

$$d = \frac{1-t}{1+t}, \quad e = \frac{1}{2t-1}, \quad f = \frac{t}{t-2}.$$

Make a change of variables  $a \rightarrow b, b \rightarrow a$  into  $L_1$  and substitute the values above; then the expression is seen to vanish. This proves that  $M_4 = 0$ . Now recall that  $\zeta^{-1}(45) \in \Theta$ , i.e., the substitution  $\zeta^{-1}(45) = (\mathbb{A} \mathbb{D})(\mathbb{B} \mathbb{E})(\mathbb{C} \mathbb{F})$  followed by  $h$  remains an alignment. This shows that  $M_5 = 0$ , and likewise for  $M_6$ .  $\square$

4.6. Now assume  $\alpha = \{1, 2, 4\}$ . We have a factorisation

$$\mathcal{C}_{124} = L'_1 L'_2 L'_4 M'_3 M'_5 M'_6,$$

with similar properties. Define the group  $G_{124}$  analogously, and let  $\mathcal{F}_{124} = \{L'_1, L'_2, L'_4, M'_3, M'_5, M'_6\}$ . As before, we have a homomorphism  $G_{124} \rightarrow \mathfrak{S}(\mathcal{F}_{124})$  given by

$$\begin{aligned} (12) &\longrightarrow (L'_1 L'_2), & (14) &\longrightarrow (L'_1 L'_4), \\ (35) &\longrightarrow (M'_3 M'_5), & (36) &\longrightarrow (M'_3 M'_6), \\ (13)(25)(46) &\longrightarrow (L'_1 M'_3)(L'_2 M'_5)(L'_4 M'_6). \end{aligned}$$

The element  $(34)$  takes the set  $\{1, 2, 3\}$  to  $\{1, 2, 4\}$ , and the change of variables induced by

$$(34) \longrightarrow (\mathbb{A} \mathbb{E})(\mathbb{B} \mathbb{C})(\mathbb{D} \mathbb{F})$$

gives a bijection  $\beta_{(3,4)} : \mathcal{F}_{123} \rightarrow \mathcal{F}_{124}$  as follows:

$$\begin{aligned} L_1 &\longrightarrow L'_1, & L_2 &\longrightarrow L'_2, & L_3 &\longrightarrow L'_4, \\ M_4 &\longrightarrow M'_3, & M_5 &\longrightarrow M'_5, & M_6 &\longrightarrow M'_6. \end{aligned}$$

In this way, the structure of each  $\mathcal{F}_\alpha$  is determined by that of  $\mathcal{F}_{123}$ . It follows that the invariance property is also true of each of the factors of  $\mathcal{C}_\alpha$ .

**Lemma 4.2.** The forms  $M_4$  and  $M'_3$  are equal (up to a scalar).

PROOF. Let  $u = (1\ 4)(2\ 5)(3\ 6)$  and  $v = (3\ 4)$ . Since  $u(L_1) = M_4$  and  $v(M_4) = M'_3$ , it would suffice to show that  $u^{-1}vu = (1\ 6)$  stabilises  $L_1$  up to a scalar. But  $(1\ 6) \longrightarrow (\mathbb{A}\ \mathbb{C})(\mathbb{B}\ \mathbb{E})(\mathbb{D}\ \mathbb{F})$ , and it is easy to see that the corresponding change of variables turns  $L_1$  into  $-L_1$ .  $\square$

In particular, if  $h$  is an alignment, then  $M'_3$  vanishes and hence so does  $\mathcal{C}_{124}$ .

**Proposition 4.3.** Assume that  $\Gamma$  is a tri-involutive sextuple. Then  $\Gamma$  satisfies CSC.

PROOF. Fix an alignment  $h$ , and consider a 3-element subset  $\alpha \subseteq \text{SIX}$ . By changing  $\alpha$  to  $\text{SIX} \setminus \alpha$  if necessary, we may assume that  $\alpha$  has at least two elements in common with  $\{1, 2, 3\}$ . But then we are in the situation above up to a change of indices, hence  $\mathcal{C}_\alpha = 0$ . (This is best seen with an example. Say,  $\alpha = \{2, 4, 6\}$ , which we may change to  $\{1, 3, 5\}$ . Now the element  $\zeta^{-1}((2\ 3)(4\ 5)) \in \Theta$  preserves  $\mathcal{F}_{123}$  and induces a bijection between  $\mathcal{F}_{124}$  and  $\mathcal{F}_{135}$ . Hence  $\mathcal{C}_{135} = 0$ .)  $\square$

This proves the implication (1)  $\Rightarrow$  (2) of the main theorem.

4.7. For the converse, assume that  $\text{LTR} \xrightarrow{h} \Gamma$  is a hexad such that each  $\mathcal{C}_\alpha$  is zero. Then (at least) one of the factors in  $\mathcal{F}_{123}$  must vanish, and we may assume it to be  $L_1$  after a change of variables. Let  $a = 1, b = 0, c = -1$  after an FLT, then (4.1) reduces to

$$L_1 = d(1 - e + 2f) - f(1 + e) = 0. \quad (4.2)$$

Now (at least) one of the six factors in  $\mathcal{F}_{124}$  must also vanish. When we pair each of them in turn with  $L_1$ , there are six cases to consider. First, assume that

$$L'_1 = d + e - f - def = 0. \quad (4.3)$$

Now these two equations have a general solution

$$d = t, \quad e = \frac{2t^2}{1+t^2}, \quad f = \frac{t(t+1)}{2t^2-t+1};$$

for a parameter  $t$ . But then

$$\mathbb{A} \rightarrow 1, \quad \mathbb{B} \rightarrow 0, \quad \mathbb{C} \rightarrow t, \quad \mathbb{D} \rightarrow -1, \quad \mathbb{E} \rightarrow \frac{t(t+1)}{2t^2-t+1}, \quad \mathbb{F} \rightarrow \frac{2t^2}{1+t^2}$$

is an alignment, and hence  $\Gamma$  must be tri-involutive. Replacing  $L'_1$  with  $L'_4, M'_5$  or  $M'_6$  leads to similar solutions, and to the same conclusion.

4.8. The remaining two cases behave a little differently. Assume that  $L_1 = 0$  as above, and

$$L'_2 = d - de - df + 2ef - def = 0.$$

The general solution is

$$d = \frac{t}{2+t}, \quad e = \frac{t-1}{t+3}, \quad f = t,$$

which by itself does not force  $\Gamma$  to be tri-involutive. However, substituting it into  $\mathcal{C}_{125}$  leads to the equation

$$\frac{(t-3)(3t-1)(3t+1)(t^2+1)^2}{(t+2)^{10}(t+3)^{11}} = 0.$$

Hence  $t$  can only be  $3, \pm\frac{1}{3}$  or  $\pm i$ . Now in fact  $\Gamma$  is tri-involutive for each of these special values; for instance, if  $t = \frac{1}{3}$  then

$$\mathbb{A} \rightarrow 1, \quad \mathbb{B} \rightarrow \frac{1}{7}, \quad \mathbb{C} \rightarrow -\frac{1}{5}, \quad \mathbb{D} \rightarrow 0, \quad \mathbb{E} \rightarrow \frac{1}{3}, \quad \mathbb{F} \rightarrow -1$$

becomes an alignment. Replacing  $L'_2$  by  $M'_3$  leads to the same inference by a similar route. In conclusion, the conditions  $\mathcal{C}_{123} = \mathcal{C}_{124} = \mathcal{C}_{125} = 0$  already force  $\Gamma$  to be tri-involutive. The main theorem is now completely proved.  $\square$

In summary, we have an assembly of homomorphisms

$$G_\alpha \longrightarrow \mathfrak{S}(\mathcal{F}_\alpha), \quad \alpha \subseteq \text{SIX};$$

and the point of the theorem lies in the interconnections between them. It is an intricate and highly regular structure on the whole, but at the moment I see no way of gaining any insight into it except by a direct computational attack as above. It would be of interest to have a more conceptual explanation for the entire phenomenon.

4.9. **The undefined  $g$ -lines.** Some of the  $g$ -lines may become undefined on a tri-involutive sextuple, i.e., the corresponding quadratic forms may vanish identically. It is easy to classify all such cases by a direct computation. Assume  $\Gamma$  to be as in §1.4.

- The line  $g(456)$  is undefined for any  $p$ ; in fact all the Kirkman points  $K[w, 456]$ ,  $w = 1, 2, 3$  coincide with the pole of the line  $Q_4Q_5Q_6$  in Figure 2.
- Additionally, if  $p = \pm i$  then  $g(\alpha)$  is undefined for every 3-element subset  $\alpha \subseteq \{3, 4, 5, 6\}$ .

For a general  $p$ , the  $g$ -lines which remain defined are not all distinct. We have

$$g(145) = g(245) = g(345)$$

and similarly with 45 replaced by 46 and 56. Thus there are only 13 distinct lines.

When  $p = \pm i$ , we have  $g(134) = g(234)$  and similarly with 34 replaced by 35, 36, 45, 46, 56. Thus there are only 10 distinct lines.

4.10. We mention another characterisation of tri-involutivity. Given a triangle  $\Delta = PQR$  in  $\mathbb{P}^2$ , let  $P'$  denote the pole of the line  $QR$  with respect to  $\mathcal{K}$ , and similarly for  $Q', R'$ . Then  $\Delta' = P'Q'R'$  is called the polar triangle of  $\Delta$ . It is a theorem due to Chasles (see [5, §7]) that these two triangles are in perspective, i.e., the lines  $PP', QQ', RR'$  are concurrent, say in a point  $\tau(\Delta) = \tau(\Delta')$ . It is also the case that the three points

$$PQ \cap P'Q', \quad PR \cap P'R', \quad QR \cap Q'R'$$

lie on the polar line of this point. In other words, the two triangles are in Desargues configuration in such a way that the point of perspectivity and the axis of perspectivity are in pole-polar relation.

**Proposition 4.4.** A sextuple  $\Gamma$  is tri-involutive, if and only if it can be decomposed into two triangles  $\Delta_1, \Delta_2$  such that  $\tau(\Delta_1) = \tau(\Delta_2)$ .

PROOF. Assume  $\Gamma$  to be tri-involutive. With  $A, \dots, F$  as in §2.3, a straightforward calculation shows that  $\tau(ABC)$  and  $\tau(DEF)$  are both represented by the form

$$T = x_1^2 - x_1 x_2 + x_2^2.$$

As to the converse, let  $\Gamma = \Delta_1 \cup \Delta_2$  be a decomposition as above. Since the construction of  $\tau$  is compatible with automorphisms of  $\mathcal{K}$ , we may assume that  $\Delta_1$  has vertices  $0, 1, \infty$  so that  $\tau(\Delta_1)$  is given by  $T$ . If  $\Delta_2$  has vertices  $u, v, w$ , then  $\Delta'_2$  corresponds to

$$(x_1 - v x_2)(x_1 - w x_2), \quad (x_1 - u x_2)(x_1 - w x_2), \quad (x_1 - u x_2)(x_1 - v x_2).$$

Since  $\tau(\Delta'_2)$  is also given by  $T$ , the three quadratic forms

$$(x_1 - u x_2)^2, \quad (x_1 - v x_2)(x_1 - w x_2), \quad T$$

must be linearly dependent and hence the  $3 \times 3$  matrix of their coefficients must have zero determinant. The same holds for the other two vertex pairs. This reduces to a set of equations

$$\beta^2 - \alpha\beta - \alpha + 3\beta + 1 = u\alpha - u - \alpha + \beta + 3 = u\beta + 1 = 0,$$

where  $\alpha = v + w$  and  $\beta = vw$ . The solutions are

$$\alpha = \frac{u^2 - 3u + 1}{u(u-1)}, \quad \beta = -\frac{1}{u},$$

implying that  $\{v, w\} = \{\frac{u-1}{u}, \frac{1}{1-u}\}$ . Hence  $\Gamma = \{0, 1, \infty, u, \frac{u-1}{u}, \frac{1}{1-u}\}$  is tri-involutive.  $\square$

The line  $Q_4Q_5Q_6$  in Figure 2 is represented by the form  $T$  (see [3, §4.5]), hence the point  $\tau(ABC) = \tau(DEF)$  is the pole of this line. It is not shown there explicitly, but in any event must lie in the interior of the conic.

## 5. THE IDEAL OF THE TRI-INVOLUTIVE LOCUS

In this section we will determine the  $SL_2$ -equivariant minimal resolution of the defining ideal of  $\Omega$  using some elimination-theoretic computations. The reader is referred to [4] for a discussion of the invariant theory of binary forms. (The set-up used there involves binary quintics rather than sextics, but the general formalism is identical.) An exposition of the same material may also be found in [19, Ch. 4].

5.1. Let

$$\mathfrak{f} = \sum_{i=0}^6 a_i \binom{6}{i} x_1^{6-i} x_2^i,$$

denote the generic binary sextic with indeterminate coefficients, and let

$$R = \mathbf{C}[a_0, \dots, a_6] = \mathbf{Sym}^\bullet(S_6),$$

denote the coordinate ring of  $\mathbb{P}^6$ . Write

$$\Psi_p = x_1 x_2 (x_1 - x_2) (x_1 - p x_2) \left(x_1 - \frac{p-1}{p} x_2\right) \left(x_1 - \frac{1}{1-p} x_2\right),$$

for the sextic form representing a tri-involutive sextuple as in §1.4.

Let  $J \subseteq R$  denote the homogeneous defining ideal of  $\Omega$ ; it consists of forms which vanish on the union of  $SL_2$ -orbits of  $\Psi_p$  taken over all  $p$ . In order to calculate it, choose indeterminates  $\alpha, \beta, \gamma, \delta$ , and make substitutions

$$x_1 \rightarrow \alpha y_1 + \beta y_2, \quad x_2 \rightarrow \gamma y_1 + \delta y_2,$$

into  $(p-1)p\Psi_p$  to get a new sextic  $\mathfrak{g}(y_1, y_2)$ . Write it as

$$\mathfrak{g}(y_1, y_2) = \sum_{i=0}^6 \binom{6}{i} \varphi_i y_1^{6-i} y_2^i,$$

where  $\varphi_i$  are polynomial expressions in the variables  $\alpha, \beta, \gamma, \delta, p$ . This defines a ring homomorphism

$$\mathbf{C}[a_0, \dots, a_6] \xrightarrow{g} \mathbf{C}[\alpha, \beta, \gamma, \delta, p], \quad a_i \longrightarrow \varphi_i,$$

so that  $J = \ker(g)$ . I have calculated this ideal explicitly in MACAULAY-2; one pleasant surprise is that it turns out to be a perfect ideal with minimal resolution

$$0 \leftarrow R/J \leftarrow R \leftarrow R(-5)^5 \leftarrow R(-6)^3 \oplus R(-7) \leftarrow 0.$$

In other words,  $\Omega$  is an arithmetically Cohen-Macaulay subvariety. Since  $\Omega$  has Hilbert polynomial

$$\frac{2}{3} t^4 - \frac{5}{6} t^3 + \frac{35}{6} t^2 - \frac{2}{3} t + 2,$$

its degree is  $\frac{2}{3} \times 4! = 16$ , in agreement with Proposition 3.2.

We should like to identify the  $SL_2$ -representation corresponding to the 5-dimensional Betti module of minimal generators in degree 5. It must be a subrepresentation of  $R_5 = \text{Sym}^5(S_6)$ . By the Cayley-Sylvester formula,

$$R_5 = S_2 \oplus S_2 \oplus S_4 \oplus \{\text{summands of dimensions } > 5\},$$

and hence on dimensional grounds the module can only be  $S_4$ . In other words,  $J$  is minimally generated by the coefficients of a covariant of degree-order  $(5, 4)$ . The complete minimal system for binary sextics is given in [8, p. 156]; it shows that there is a unique such covariant up to a scalar. It can be described as follows: define

$$\vartheta_{24} = (\mathfrak{f}, \mathfrak{f})_4, \quad \vartheta_{32} = (\vartheta_{24}, \mathfrak{f})_4, \quad \vartheta_{54} = (\vartheta_{24}, \vartheta_{32})_1,$$

where  $\vartheta_{mq}$  is of degree-order  $(m, q)$ . Thus  $J$  must be generated by the coefficients of  $\vartheta_{54}$ . This implies that  $\Gamma = \{z_1, \dots, z_6\}$  is tri-involutive exactly when the covariant  $\vartheta_{54}$  vanishes identically on the sextic  $\prod_{i=1}^6 (x_1 - z_i x_2)$ .

The resolution shows that  $J$  has a three-dimensional space of linear syzygies, and a unique quadratic syzygy. In order to find the former, we must look for an identical relation of the form  $(\vartheta_{54}, \mathfrak{f})_r = 0$ . Since binary sextics has no covariant of degree-order  $(6, 2)$ , perforce  $(\vartheta_{54}, \mathfrak{f})_4 = 0$ . The quadratic syzygy is similarly accounted for by the identity  $(\vartheta_{54}, \vartheta_{24})_4 = 0$ , since there is no invariant in degree 7. In summary, the equivariant minimal resolution of  $J$  is

$$0 \leftarrow R/J \leftarrow R \leftarrow R(-5) \otimes S_4 \leftarrow R(-6) \otimes S_2 \oplus R(-7) \leftarrow 0.$$

5.2. Since  $\vartheta_{54}$  is defined to be the Jacobian of  $\vartheta_{24}$  and  $\vartheta_{32}$ , its vanishing implies a functional dependency between the latter two. This is confirmed by a direct computation. Indeed,

$$\vartheta_{24}(\Psi_p) = f_1(p) T^2, \quad \text{and} \quad \vartheta_{32}(\Psi_p) = f_2(p) T,$$

where  $T = x_1^2 - x_1 x_2 + x_2^2$  as in §4.10, and the  $f_i$  are rational functions of  $p$ . Thus, when  $\mathfrak{f}$  is specialised to a tri-involutive sextuple,  $\vartheta_{32}$  evaluates to a quadratic form which corresponds to the line containing its three centres of involution.

5.3. A special case deserves to be mentioned. The precise value of  $f_1(p)$  is

$$f_1(p) = \frac{(p^2 + 1)(p^2 - 2p + 2)(2p^2 - 2p + 1)}{p^2(p - 1)^2},$$

which vanishes for

$$p = \pm i, \quad 1 \pm i, \quad \frac{1}{2}(1 \pm i). \tag{5.1}$$

Thus  $\vartheta_{24}$  and  $\vartheta_{32}$  are both identically zero for these values of  $p$ , suggesting that the line containing the three centres becomes ‘indeterminate’ in some sense. As we will see, this is indeed so.

Specialise to  $p = i$ , i.e., let

$$A = 0, \quad B = 1, \quad C = \infty, \quad D = i, \quad E = \frac{i-1}{i} = 1+i, \quad F = \frac{1}{1-i} = \frac{1}{2}(1+i).$$

We have already seen in §4.10 that  $\underbrace{\tau(ABC) = \tau(DEF)}_{T_1}$  for any  $p$ . However, a direct calculation shows that in this case we additionally have

$$\underbrace{\tau(ADF) = \tau(BCE)}_{T_2}, \quad \underbrace{\tau(ACD) = \tau(BEF)}_{T_3}, \quad \underbrace{\tau(ABF) = \tau(CDE)}_{T_4}.$$

Thus  $\Gamma$  has altogether twelve centres of involution, which lie by threes on four lines.

The group  $\Theta(i)$  is strictly larger than the generic case. It is easily seen that  $(\mathbb{A} \mathbb{E})$  and  $(\mathbb{C} \mathbb{F})$  are in  $\Theta(i)$ ; either element will turn all cross-ratios in (3.1) into  $-i$ . Then it follows automatically that  $(\mathbb{B} \mathbb{D}) \in \Theta(i)$ . If  $V$  denotes the group generated by these two transpositions (so that  $V$  is isomorphic to the Klein four-group), then  $\Theta(i)$  is the internal direct product of  $\Theta$  and  $V$ . Hence  $|\Theta(i)| = 144$ .

The group  $V$  permutes the four lines; for instance, transposing  $A$  and  $E$  will turn the pair of triangles  $ABC, DEF$  into  $BCE, ADF$ . The morphism  $V \longrightarrow \mathfrak{S}(\{T_1, T_2, T_3, T_4\})$  is given by

$$(\mathbb{A} \mathbb{E}) \longrightarrow (T_1 T_2) (T_3 T_4), \quad (\mathbb{C} \mathbb{F}) \longrightarrow (T_1 T_4) (T_2 T_3).$$

5.4. In fact all the forms  $\Psi_p$  for any of the six values given in (5.1) lie in the same  $SL_2$ -orbit in  $\mathbb{P}^6$ , which we denote by  $\mathcal{Z}$ . This is a well-known geometric object. The orbit is Zariski closed in  $\mathbb{P}^6$ ; indeed there are very few orbits of binary forms which have this property, and they have all been classified in [1]. (There it is described as the orbit of  $x_1^5 x_2 - x_1 x_2^5$ , which comes to the same thing.) Moreover,  $\mathcal{Z} \subseteq \mathbb{P}^6$  is an arithmetically Gorenstein subvariety in codimension 3, and its ideal  $I$  is generated by the coefficients of  $\vartheta_{24}$  (see [13, §3]). It has a self-dual Buchsbaum-Eisenbud resolution

$$0 \leftarrow R/I \leftarrow R \leftarrow R(-2) \otimes S_4 \leftarrow R(-3) \otimes S_4 \leftarrow R(-5) \leftarrow 0.$$

Unfortunately one cannot draw a diagram of this sextuple and its twelve centres of involution, since the equality  $\langle A, B, C, F \rangle = i$  implies that not all six points can be chosen to be simultaneously real.
